## ABSTRACT

*This paper described the identification of the maximum value of stress that acts at the wing-fuselage joints. The finite element models of the wing, the wing lugs and the fuselage lugs were developed. Finite Element Analyses were performed using NASTRAN finite element software. CQUAD4 and BAR2 elements were used to represent the individual structures of the wing such as the ribs and stringers are presented in detail in this paper. The applied load was based on 1-g symmetric level flight condition that was the load applied at the wing is equal to the net weight of the aircraft. Once the load distribution acting at the wing have been calculated and applied, reaction forces at the nodes representing the wing lugs are obtained and these values are applied to the lug models where the maximum stress value acting at the lugs was obtained. This stress value can be further used for fatigue calculations.*

**Keywords:** *Wing-fuselage joints, finite element analysis*

## **Introduction**

The use of finite element analysis (FEA) has made its way to a stage where it has widely been used in solving various engineering problems. The usage of FEA keeps improving steadily over the past few decades. There are many references that can be found to better understand the concept of using finite element as an analysis tool [1]. It is a form of numerical analysis which can be used for stress prediction and structure optimization [2].

Finite Element Analysis can be used to solve all types of linear and nonlinear stress, dynamics, composite and thermal engineering analysis problem. Its application varies depending on the type of analysis to be performed. The behaviors of different materials under variable conditions are able to be predicted. The application of such an analysis tool in the aircraft industry, such as MSC. NASTRAN [3], which predicts the behavior of structures at component level. It has been used effectively in different types of analysis of aircraft structures. Analysis conducted by Fleming et. al. concentrated on the aircraft fuselage panel [4], while Kuntjoro et. al. performed analysis on the structural design of the wing panel [5] and Buehrle et. al. carried out analysis on aircraft fuselage structures [6]. The Finite Element Analysis tool would also be able to assist engineers in providing valuable data to be used for large experiments, for example the SWISS F/A-18 full scale fatigue test program [7].

The finite element tool such as MSC.Nastran can be used as a part of the process of fatigue life prediction (FLEI) of the aircraft. This will involve the monitoring of crack initiation or fatigue life of a component, for example, the wing-fuselage joints (lugs). In order to satisfy this purpose, the maximum stress occurring at the wing-fuselage joints (lugs) at 1-G symmetrical level flight condition needs to be obtained. The outcome of this analysis can be used for the stress-spectra generation [8] or to carry out further fatigue analysis [9]. The Finite Element Analysis is employed to determine the maximum stress value of the lugs. The finite element model of the wing, the wing lugs and the fuselage lugs was developed in this paper. The load applied to the wing is derived. The reaction forces obtained from the wing analysis will be applied to the wing-side lug and fuselage-side lug respectively. In this analysis, MSC. Nastran is used to predict the maximum stress occurring at the wing fuselage joints (lugs) of an aircraft.

## **Methodology**

Figure 1 shows the layout of the aircraft which consists of the aircraft wing, the wing-side lug and the fuselage-side lug.

Figure1: Aircraft layout

Figure 2: Component of fatigue analysis

The methodology to perform the 1-G stress prediction is actually a part of the process to predict the life of a component as shown in Figure 2. The procedure for the 1-G stress prediction analysis is as follows. First, the wing loading at 1-G symmetrical level flight condition is predicted. Then the finite element model of the wing is developed and the finite element analysis is carried out on the wing. Then, it follows with the development of the finite element model of the lugs of the wing and fuselage. The reaction force that was obtained from the wing analysis are then applied to both the wing and fuselage lugs. From here, the maximum stress value is identified.

### Finite element model of wing and lugs

The analysis of the finite element of the wing and the wing-fuselage lugs are as follows:

### Wing loading at 1-g symmetrical level flight condition

An example of calculations for the load to be applied is as follows:

The maximum take-off weight of the aircraft ( $W$ ) = 18000 kg = 18000 × 9.81 = 176580 N

Total force acting on the wing =

$$\frac{\text{Wing Model Area}}{\text{Half Wing Area}} \times \frac{W}{2} \quad (1)$$

- $a$  = Net Load acting on wing
- $b$  = Total force acting on the wing (1)
- $c$  = The weight of fuel of the plane is assumed to be stored at the wing region being analyzed
- $d$  = The weight of weapons of the aircraft that are placed at the wing region being analyzed
- $e$  = The weight of the wing structure

$$a = b - c - d - e$$

The force is distributed in such a manner where the load magnitude is higher at the wing region which is closest to the fuselage and continuously decreasing outboard until the wing tip.

For 21 sections along the span of the wing, Figure 3, the forces are distributed according to the chord length of that particular section. If the chord length is higher, then the forces applied would be higher. The longest chord closest to the fuselage is 2862.78 mm and the length of the chord nearer to the tip is 1076.46 mm.

Figure 3: Wing model showing points of loads

### Finite element model of the wing

The finite element model of the wing, Figure 4, was created with the following properties [10]:

- i. *The upper skin, lower skin, ribs surfaces, leading edge, trailing edge and the wing tip* are comprised of CQUAD4 elements. The CQUAD4 is MSC Nastran's most commonly used element for modeling plates, shells and membranes. The CQUAD4 can represent in-plane, bending, transverse shear behavior, depending upon data provided on the PShell property entry. This element is a quadrilateral flat plate connecting four grid points.
- ii. *CSHEAR panel* to represent the forward, center and aft spar with thickness of the spar varying from 5mm to 2mm from the wing region next to the fuselage down to the wing tip. CSHEAR is a four-grid element that supports shear and extensional force.
- iii. *BAR2 element* to represent the stringers with 1-d rod property of area 73.28 mm<sup>2</sup> and the ribs' stiffeners with 1-d rod property of area 100mm<sup>2</sup> (representing the effective areas of the ribs stiffeners and stringers). The BAR element is a general purpose beam that supports tension and compression, torsion, bending in two perpendicular planes, and shear in two perpendicular planes. The BAR connects two grid points, and can provide stiffness to all six DOFs of each grid point. The CROD element is connected by two grid points, and supports axial force and axial torsion.
- iv. *The ribs surfaces* are presented by shell property of thickness 1mm. The PSHELL entry defines the membranes, bending, transverse shear, and coupling properties of thin plate and shell elements.

Figure 4: Finite element model of the wing

- v. *The skin*, the leading and trailing edge are represented by shell property of thickness 2 mm.
- vi. *The material* used for this analysis is Aluminum Alloy 7000 series with a Young Modulus of 72 GN/m<sup>2</sup> and Poisson Ratio of 0.33. It is assumed that there are no changes in the material properties due to changes in atmospheric temperatures and pressures of different altitudes.
- vii. *The model* is fixed at the points representing the location of the lugs and loads are applied accordingly (at  $z$  direction of this model).

Finite Element Analysis is performed on the wing, with the wing-fuselage lug joints are regarded as wing supports. The results of the reaction forces of the supports are obtained. This will be presented more detailed at the Results and Discussion section.

### Finite element model of the lugs of the wing and fuselage

In order to identify which lug is the most critical, analysis must be done on all the lugs, both on the fuselage side and the wing side. From the analysis of the wing, the highest force is acting on the *aft* side of the lug which means that it is most likely for the critical lug to be on the aft side. Aft is defined as the back section of the aircraft. Nevertheless analyses on all the lugs were carried out. The finite element models of the wing lug and fuselage lug are shown in Figure 5. The lugs are comprised of wing side lugs and the fuselage side lugs. As for reference, both the wing-side and the fuselage-side lugs are represented by outer, center and inner lugs where the outer lug is facing forward of the aircraft and inner lug is facing aft of the aircraft (Figure 6 and Figure 7).

The Coupled Pressures are applied at the lugs at the  $x$  and the  $y$  direction. The pressures act on opposite directions at the wing-side and fuselage-side lugs. The values of the pressures applied vary depending on its position being in the

Figure 5: Finite element models of the lugs

forward, center or aft. The maximum *von Mises* stress value is presented. Von Mises is the norm value for stress which is equivalent to a norm of a vector or a tensor.

### Wing-side lug

Each of the wing-side lugs consists of three parts. For referencing purposes, it shall be labeled as the inner, center and outer lugs. This means that each forward, center and aft section where the lugs are situated will consist of forward inner lug, forward center lug, forward outer lug, center inner lug, center center lug, center outer lug, aft inner lug, aft center lug and aft outer lug (Figure 6).

Figure 6: Location of wing-side lugs for reference

The geometry of the each three parts differs from one another but is assumed to be similar for the forward, center and aft section of the aircraft where the lugs are located. The material used for this analysis is a titanium alloy, Ti-6-22-22S which has a Young Modulus of 113.8e9 Pa and Poisson Ratio of 0.33. It is assumed that there are no changes in the material properties due to changes in atmospheric temperatures and pressures of different altitudes.

### Fuselage-Side Lug

Each of the wing-side lugs consists of two parts. For referencing purposes, it shall be labeled as the inner and outer lugs. This means that each forward, center and aft section where the lugs are situated will consist of forward inner lug, forward outer lug, center inner lug, center outer lug, aft inner lug and aft outer lug (Figure 7).

Figure 7: Location of fuselage-side lugs for reference

The geometry of the each two parts differs from one another and is different for forward, center and aft section of the aircraft where the lugs are located. The material used for this analysis is Stainless Steel which has a Young Modulus of  $210 \times 10^9$  Pa and Poisson Ratio of 0.33. It is assumed that there are no changes in the material properties due to changes in atmospheric temperatures and pressures of different altitudes.

## **Reaction Forces Obtained from the Wing Analysis**

Once the reaction forces have been obtained from the finite element analysis of the wing, the values are applied to the wing-side lug and the fuselage side lug accordingly. Once analyses have been carried out on all the lugs, the maximum value of stress is obtained.

## Results and Discussion

The loads to be applied to the wing are obtained from the calculations in section 3.1. The net Load acting on the wing is equal to 15000 N. Forces Acting at Section 1 to 21 along the wing are tabulated below, Table 1:

Table 1: Forces acted along the wing

Section	Force (N/node)	Section	Force (N/node)
1	211.9	12	133
2	204.5	13	127.3
3	197.2	14	121.3
4	190	15	115.3
5	182.6	16	109.4
6	175.4	17	103.4
7	168.1	18	97.5
8	160.8	19	91.5
9	153.6	20	85.6
10	146.4	21	79.7
11	139.2		

From Figure 8 and 9, reaction forces that are obtained from the wing analysis were in the  $y$  and the  $z$  direction. These forces are applied to the wing-side lugs and the fuselage-side lugs. The calculations of the specific force to be applied to each lug are presented.

Figure 8: Forces acting at the Y-direction

Figure 9: Forces acting at the Z-direction

The reaction forces that are acting at the nodes representing the wing-side lugs are presented in Table 2 below:

Table 2: Results of reaction forces from the wing analysis

Lugs Position		Reaction Forces in the Y – Direction (N)	Reaction Forces in the Z – Direction (N)
Forward	Top	23900	808
	Bottom	23900	1020
Center	Top	41500	2880
	Bottom	41500	2820
Aft	Top	46700	3690
	Bottom	46700	3470

The total force acted in the z direction is 14968 N which was less than 5% of the error of the total applied load of 15000 N. These are the values that are used when applying the forces to the forward, center and aft lugs of the wing-side and the fuselage side of the aircraft. Due to the geometry and coordinates reference of the models, the reaction forces that are obtained in the y direction of the wing are applied as the x direction of the lugs and the reaction forces obtained in the z direction of the wing are applied as the y direction of the lugs. These forces are converted to pressures and applied accordingly. The pressures applied to the wing-side lugs of the wing are tabulated in Table 3.

The pressures applied to the fuselage-side lugs are tabulated in Table 4. Once all of the values have been applied to all the lugs, the maximum value of

Table 3: Pressures applied to the wing-side lug

Lugs Position			Pressures in the $X$ – Direction (N/mm <sup>2</sup> )	Pressures in the $Z$ – Direction (N/mm <sup>2</sup> )

		Bottom	172.1	13.56

the von Mises stress was obtained. As shown in Figure 10, the maximum von Mises stress is 130 MN/m<sup>2</sup>.

Figure 10: Maximum von mises stress

## Conclusion

The maximum stress value acted at the wing and fuselage lugs has successfully been determined using all parameters obtained from the modelling of the wing, wing side lugs and fuselage side lugs. This paper has proven the effectiveness of using a finite element analysis tool.

# **JOURNAL OF MECHANICAL ENGINEERING (JMechE)**

## **Aims & Scope**

Journal of Mechanical Engineering (formerly known as Journal of Faculty of Mechanical Engineering) or JMechE, is an international journal which provides a forum for researchers and academicians worldwide to publish the research findings and the educational methods they are engaged in. This Journal acts as a vital link for the mechanical engineering community for rapid dissemination of their academic pursuits.

Contributions are invited from various disciplines that are allied to mechanical engineering. The contributions should be based on original research works. All papers submitted to JMechE are subjected to a reviewing process through a worldwide network of specialized and competent referees. To be considered for publication, each paper should have at least two positive referee's assessments.

## **General Instructions**

Manuscripts intended for publication in JMechE should be written in camera ready form with production-quality figures and done electronically in Microsoft Word 2000 (or above) and submitted online to [jmeche.int@gmail.com](mailto:jmeche.int@gmail.com). Manuscripts should follow the JMechE template.

All papers must be submitted online to **[jmeche.int@gmail.com](mailto:jmeche.int@gmail.com)**

Correspondence Address:

# **Paper Title in Arial 18-point, Bold and Centered**

*Author-1*

*Author-2*

*Affiliation of author(s) from the first institution*

*Author-3*

*Affiliation of the author(s) from the second institution  
in Times New Roman 10 italic*

## **ABSTRACT**

*The first section of the manuscript should be an abstract, where the aims, scope and conclusions of the papers are shortly outlined, normally between 200 and 300 words. TNR-10 italic*

**Keywords:** *maximum 5 keywords.*

## **Title of First Section (Arial 11 Bold)**

Leave one blank line between the heading and the first line of the text. No indent on the first para after the title; 10 mm indent for the subsequent para. At the end of the section, leave two blank lines before the next section heading. The text should be right and left justified. The recommended font is Times New Roman, 10 points. In 152 mm x 277 mm paper size, the margins are: left and upper: 22 mm each; right: 20 mm, lower: 25 mm.

## **Secondary headings (Arial 10 Bold)**

The text starts in the immediately following line. Leave one blank line before each secondary heading.

## **Tertiary headings (Arial 10)**

If they are required, the tertiary headings shall be underlined. Leave one blank line before tertiary headings. Please, do not use more than three levels of headings, try to keep a simple scheme.

Tables and illustrations should be numbered with arabic numbers. Tables and illustrations should be centred with illustration numbers written one blank

line, centered, after the relevant illustration. Table number written one line, centered, before the relevant table. Leave two blank lines before the table or illustration. Beware that the proceedings will be printed in black and white. Make sure that the interpretation of graphs does not depend on colour. In the text, tables and figures should be referred to as Figure 1 and Table 1.

The International System of Units (SI) is to be used; other units can be used only after SI indications, and should be added in parenthesis.

Equations should be typed and all symbols should be explained within the manuscript. An equation should be preceded and followed by one blank line, and should be referred to, in the text, in the form Equation (1).

$$y = A + Bx + Cx^2 \quad (1)$$

Last point: the references. In the text, the references should be a number within square brackets, e.g. [3], or [4]–[6] or [2, 3]. The references should be listed in numerical order at the end of the paper.

Journal references should include all the surnames of authors and their initials, year of publication in parenthesis, full paper title within quotes, full or abbreviated title of the journal, volume number, issue number and pages. Examples below show the format for references including books and proceedings.
